Digital Image Fundamentals

2.1 Light and the Electromagnetic Spectrum

- 4 The nature of light reflected by the object determines the colors that we perceive. A body may reflect
- 5 balanced or unbalanced type of light. The object that returns balanced type of light appears brighter than
- 6 the object that reflects unbalanced light. There are different types of images that can be categorized as:
 - Grayscale images (monochrome images)
 - Color images
 - Multi-channel images

10 2.1.1 Grayscale images

- 11 In monochromatic or achromatic light colors are absent whereas chromatic light contains various
- 12 colors. There are some attributes that are associated with achromatic light as listed below.
 - Intensity of achromatic light determines its amount known as level.
 - There are 256 *levels* in a monochromatic image and these levels are called the gray scale
 - An image formed using gray scale is known as grayscale image

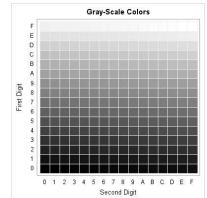

Figure 2-1: Grayscale matrix

Similarly, the chromatic light has some associated characteristics that include.

- Frequency: Chromatic (color) light spans the electromagnetic energy spectrum from approximately 0.43 to 0.79 mm
- Radiance is the total amount of energy that flows from the light source, and it is usually measured in watts (W)
- Luminance gives a measure of the amount of energy an observer perceives from a light source and is measured in lumens (lm).
- Brightness is a subjective descriptor of light perception that is practically impossible to measure

A prominent method of image generation is based on measuring the light intensity incident on some light sensitive device. However, it is not only method and there are other sources that can be used to generate images that may include the sound waves, electron beams for electron microscopy and software based virtual image generation.

- 1 2.1.2 Color images
- 2 Color images are formed using monochrome images. In ordinary color image, there are three
- 3 monochrome images: red, green and blue. There are different color spaces (schemes to represent color
- 4 images), however simple and commonly used color scheme is RGB.

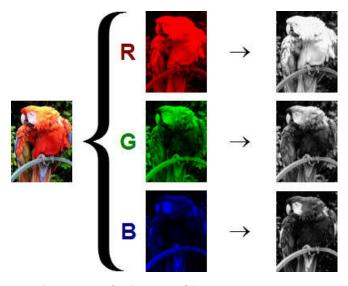

Figure 2-2: Color image and its R, G,B components

When each color component is visualized separately, it is shown as gray image. A color image is collection of three images as shown in figure 2-2. Like grayscale image, each image in color image has intensity values ranging from 0-255. Each sub image is also called the channel. Hence, we can say that a color image has three channels.

2.1.3 Multi-channel images

12 Color images have usually three channels, however, there are other type of images that contain more 13 than 3 channels. Example of such images include the CT scans or MRI scans. A brain MRI image may

contain 100 or more channels. In medical domain, these channels are named as slices.

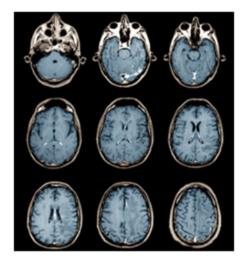

Figure 2-3: Human brain multi-slice MRI

You may have seen such images. In these images, each slice (channel) is shown separately on the film.

2.2 Image Sensing and Acquisition

- 5 Images can be acquired using single sensing elements (photodiode) or an array of sensing elements. When
- a light wave strikes a photo diode, it produces voltage that is proportional to intensity of light. The
- 7 selectivity of sensor can be improved by using a filter in front of diode.
- 8 A linear sensor can capture the light coming from a linear source. We can think of linear sensor as "line"
- 9 imaging device.

10 11

16 17

18 19

20

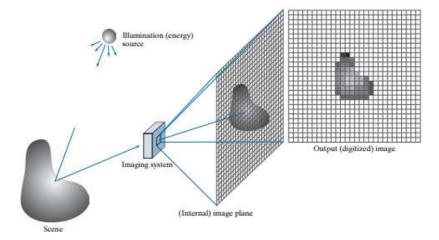

21

Figure 2-4: A) Single photo diode B) 1D Array of Photo Diodes C) A 2D Matrix of Light Sensing Elements (Photo

- 12 Diodes)
- And finally, if the diodes are arranged in the form of a matrix, a 2D image can be constructed.

14 2.2.1 Image formation Model

An image can be considered as 2D function f(x,y). x,y denote the position of pixel which is discrete. For example, in above picture, position of each diode determines the position of pixel. The position of a diode in row one and column one can be denoted as f(0,0) [or f(1,1) if indexing starts from 1] and the value of light intensity on that diode is the value of corresponding pixel located at position (0,0) in image. Image pixel values are normally non-negative however it depends upon the intensity interpretation scheme that we use. If we use negative values to represent some levels and positive values for remaining levels, our image may contain negative intensity values.

sajidiqbal.pk@gmail.com

- 1 There are two factors that affect the value of f(x, y).
 - Illumination i(x, y): The amount of source illumination incident on the scene being viewed, and
 - Reflectance r(x, y): The amount of illumination reflected by the objects in the scene
- 5 An image f(x, y) is formed as product of these two components

$$f(x,y) = i(x,y)r(x,y)$$
 (2-1)

- 7 Where $0 < i(x, y) < \infty$ and 0 < r(x, y) < 1
- 8 Although theoretically intensity i(x, y) could be zero to infinite however practically, we define its finite
- 9 discrete levels i.e.

$$10 0 < i(x, y) < Lmax$$

11 Or equivalently

$$12 Lmin < i(x, y) < Lmax$$

- Generally, the interval [Lmin, Lmax] define the gray scale. Normally this interval is taken as
- 14 [0,1] or [0,C] where C is some upper limit on level count i.e. 255.
- 15 2.2.2 Sampling and Quantization
- 16 A computer is a machine that work with discrete quantitates however most of the quantities occurring in
- our real life are continuous in nature. For example, intensity of light, temperature and amount of water.
- 18 It is required to convert continuous quantities into discrete for computer processing.
 - *Sampling*: it is the process of measuring a continuous quantity or signal after equal intervals of time. For example, we can measure intensity of light after every one second.
 - *Quantization*: Continuous quantity measured after equal intervals of time may be fractional. For example, in one second you measure intensity of light that is 5 and after next second, it is measured as 5.8. In order to make computer processing better and efficient, it is required to round such fractional quantities to complete quantities.
- 25 Similarly, when light is made incident on a 2D matrix of photo diodes as shown in Figure 2-4, it is required
- to measure the light intensity in equal intervals of time and then quantize them into discrete levels. Figure
- 27 2-6 shows this description pictorially.

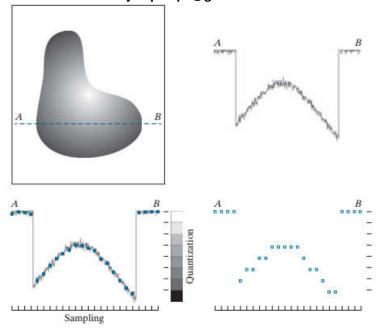

Figure 2-6: Image Sampling and Quantization

Following figure 2-5 shows a continuous image and its equivalent digitization.

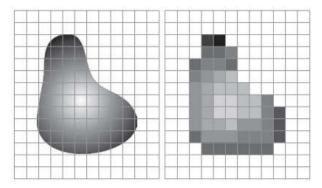

Figure 2-7: Continuous Image and its Digitization

2.2.3 Representing Digital Images

Let f(s,t) is the function that represents the continuous image and f(x,y) is its equivalent representation in discrete form obtained after sampling and digitization. Let there are M rows and N columns in resulting digital image. A matrix of discrete values can represent the digital image. This matrix will contain the sampled and quantized values of intensity of light incident on each sensor. If we index the sensors starting from zero, then f(0,0) will represent the value of light intensity incident on first sensor.

13
$$f(x,y) = \begin{bmatrix} f(0,0) & \cdots & f(0,N-1) \\ \vdots & \ddots & \vdots \\ f(M-1,0) & \cdots & f(M-1,N-1) \end{bmatrix}$$
 2-2

If you find any mistake in this text or you have any suggestions for improvement, please email me at

sajidiqbal.pk@gmail.com

There are different notations that can be used to represent the digital image in the form of unsigned integer values. Here is another notation of image.

3
$$f(x,y) = \begin{bmatrix} a_{0,0} & \cdots & a_{0,N-1} \\ \vdots & \ddots & \vdots \\ a_{M-1,0} & \cdots & a_{M-1,N-1} \end{bmatrix}$$
 2-3

4

6

7

8

9

10

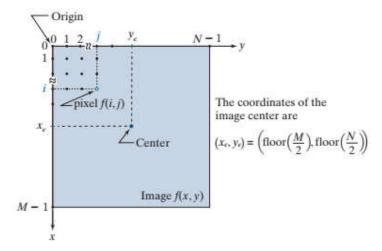

11 12

13

14

15

- 5 There are few characteristics associated with this image representation in matrix form.
 - Each single diode represents a value for a pixel
 - Each pixel value is unsigned integer normally ranging from 0-255 or in normalized form 0-1
 - Indexing of image pixel starts form top-left corner
 - Such image representation is also known as representation in *spatial domain*
 - Number of intensity levels are denoted as $L=2^k$ where k is the number of bits used to store the value of a pixel. Total number of bits required to store an image is MxNxk where M is the number of rows, N is the number of columns and k is the number of bits used to store value of one pixel.
 - Dynamic range: It represents the highest and lowest intensity levels that an image can have.
 - Intensity Contrast: It is the difference between lowest and highest intensity level in an image
 - Contrast Ratio: it is the ratio of highest and lowest intensity levels present in the image.

16 17

18

19

20

21

Figure 2-8: Image Representation and its Characteristics

- It is to note that figure 2-8 shows the axis in different way than usual Cartesian plane. Here x-axis is shown in vertical direction and y-axis is shown in horizontal direction. The way of this representation is in accordance with data representation in programming language. For example, in a programming language like python a 2D matrix is shown as:
- 22 $A = \begin{bmatrix} [a_{00} & a_{01} & a_{02}] \\ [a_{10} & a_{11} & a_{12}] \\ [a_{20} & a_{21} & a_{22}] \end{bmatrix}$ 2-4

In this representation, first index shows the row number and second index shows the column number.

Now when row number increases, we move in downward direction and when column number increases,

we move in horizontal direction. You must be careful when indexing image data i.e.

Change in first index will move along vertical direction and change in second index will move along horizontal data.

2.2.4 Spatial and Intensity Resolution

There are two type of resolutions (details) that we can consider in the context of an image.

- *Spatial Resolution*: This defines the number of pixels in unit area. For example, the number of pixels that can be drawn in a millimeter area. More the pixels, higher the resolution. It can be measured in dots per inch.
- Intensity Resolution: It defines the number of intensity levels that are present in the image. For example, an image has intensity levels in the interval [0-255], its resolution is 255 whereas another image having intensity levels from [0-1000] and such an image has intensity levels 1000. Usually the intensity levels are power of 2.

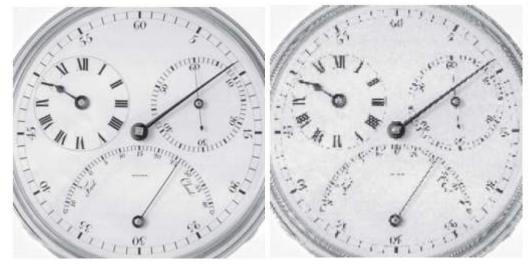

Figure 2-9: A) High Spatial Resolution Image - 930 dpi B) Low Resolution Image - 72 dpi

And following figure shows two images having different intensity resolutions

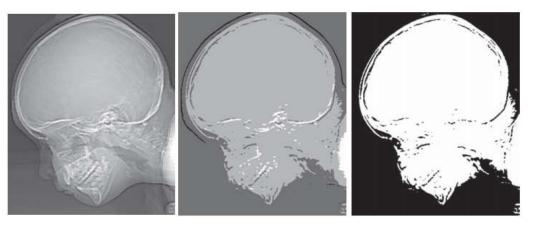

Figure 2-10: Intensity Resolution. A) 256 Level Image B) 4 Intensity Levels C) 2 Intensity Levels

If you find any mistake in this text or you have any suggestions for improvement, please email me at

sajidiqbal.pk@gmail.com

- 1 There are some concepts associated with intensity resolutions:
 - Contours: It is an outline representing or bounding the shape or form of something
 - *False Contours*: With the decrease of intensity resolution, very fine ridge-like structures in areas of constant intensity are introduced (false lines) which are named as false contours
 - Image information: Due to nature of image the level of information present in an image may vary. There is no well-defined limit however some images contain more information whereas other contain less information

15 2.3 Pixels and their relationships

- 16 There are different types of relationships that can exist among the pixels. This relationship is normally
- 17 based on some type of criteria that we define.
- 18 2.3.1 Adjacency
- 19 Adjacency is the relationship of two pixels that defines the nearness. Depending upon the criteria we
- define, adjacency of two pixels is found. For example, intensity-based adjacency may define the closeness
- 21 of two pixels whether they have similar intensity values or not. For Spatial adjacency, pixels are related to
- 22 each other based on their location in the image.
- 23 2.3.2 4-neighbour relationship $N_4(p)$
- A set of pixels that is found in four different directions from reference pixel is called 4-neighbourhood.
- 25 Following table shows the four neighborhoods of a pixel.

27
$$N_4(p) = (f(x, y-1), f(x-1, y), f(x+1, y), f(x, y+1))$$
 2-5

sajidiqbal.pk@gmail.com

Table 1: 4-Neighbourhood of a pixel

	f(x,y-1)	
f(x-1,y)	f(x,y)	f(x+1,y)
	f(x,y+1)	

- 2 2.3.3 8-neighbour relationship $N_8(p) = N_4(p) \cup N_D(p)$
- 3 A set of pixels that is found in eight different directions from reference pixel is called 4-neighbourhood.
- 4 Following table shows the four neighborhoods of a pixel.

$$N_8(p) = \begin{bmatrix} f(x-1,y-1), f(x,y-1), f(x+1,y-1), \\ f(x-1,y), f(x+1,y) \\ f(x-1,y+1)f(x,y+1)f(x+1,y+1) \end{bmatrix} 2-6$$

Table 2: 4-Neighbourhood of a pixel

f(x-1,y-1)	f(x,y-1)	f(x+1,y-1)
f(x-1,y)	f(x,y)	f(x+1,y)
f(x-1,y+1)	f(x,y+1)	f(x+1,y+1)

7

5

6

- If a neighborhood set of a pixel *p* contains p itself, it is called *closed* neighborhood and if *p* is not contained in the neighborhood set, it is called *open* neighborhood.
- 10 2.3.4 m-neighbor relationship
- 11 It is also called m-adjacency (mixed adjacency). It is modification of 8-adjacency which is introduced to
- 12 eliminate the ambiguities that often arise when 8-adjacency is used. Let V define the set of intensities
- 13 that determine the adjacency (if two pixels have intensity values from that set, they are said to be
- adjacent). Two pixels p and q are said to be m-adjacent if they meet following conditions:
- 15 1. q is in $N_4(p)$ OR
 - 2. q is in $N_D(p)$ and the set $R = N_A(p) \cap N_A(q) = \emptyset$ if $Intensity(R) \in V$
- Two conditions need to be fulfilled. If a pixel q is in 4-neighbours of p, it is in m-adjacency. Second condition has two parts
 - p, q are in diagonals of each other and
 - There should be no pixel which is in 4-adjacency of both and have pixel value from set *V*.

Example 2-1: m-Adjacency

22

25

16

19

20

21

Let if set of intensities $V = \{1\}$ then

$$\begin{bmatrix} 0 & 1 & 1_q \\ 0 & 1_p & 0 \\ 0 & 0 & 1 \end{bmatrix} \rightarrow \begin{bmatrix} 0 & 1 & 1_q \\ 0 & 1_p & 0 \\ 0 & 0 & 1 \end{bmatrix} \rightarrow \begin{bmatrix} 0 & 1 & 1_q \\ 0 & 1_p & 0 \\ 0 & 0 & 1 \end{bmatrix}$$

Condition-1: q must be in 4-adjacency in order to be in m-adjacency. (false)

If you find any mistake in this text or you have any suggestions for improvement, please email me at sajidiqbal.pk@gmail.com

• Condition-2:

- o A) q is in diagonals of p
- B) There are two pixels which are common i.e. $N_4(p) \cap N_4(q) = \{1,0\}$ that are shown as red. Now part-2 of condition-2 says that if there are any common points in four-neighborhood of both p and q, their intensities must not be from V. In our example, there are two common pixels with intensity 0 and 1. Intensity "0" is not in our set V, hence it satisfies the condition for q to be in m-adjacency. But intensity "1" is from set V and it violates the condition therefore, \mathbf{p} and \mathbf{q} are not in m-adjacency hence their direct path is removed. Note that p,q are in 8-adjacency but not in m-adjacency.

2.3.5 Digital Path

If there exists a set of mutually adjacent pixels P between two pixels p and q such that we can reach from p to q by following the adjacency, the set of pixels is called the path P.

$$P = \{(x_0, y_0), (x_1, y_1), \dots, (x_n, y_n)\}$$
2-7

For valid path, a criterion may be defined that every pixel in path must have intensity values from a specified set V. For example, if $V = \{2,3\}$, and we want to find path from p to q. All pixel that lie in path must have intensity value that lie in V i.e. 2 or 3. Any other value will break the path.

The number of pixels in P is called the *length of path*. The path could be *open* if $(x_0, y_0) \neq (x_n, y_n)$ otherwise the path is *closed*.

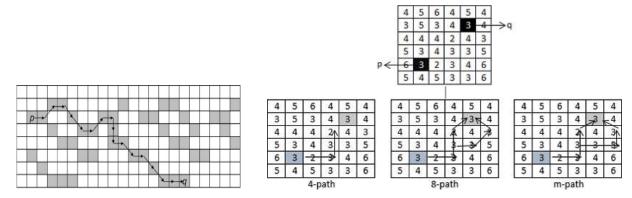

Figure 2-12: A) Digital Path B) Path and its types

- For a pixel p, in 4-path, path direction can be in any of $N_4(p)$
 - Similarly, for 8-path, next pixel could be in any of $N_8(p)$ direction
 - And in m-path, any mixed direction could be used.

2.3.6 Connected component

For a particular image, if there exists a path between two pixels, the pixels are said to be *connected*. The set of pixels that are connected with each other is called the *connected component*. There may be one or more such connected components in the image. If there is only one such set, it is referred as *connected set*.

If you find any mistake in this text or you have any suggestions for improvement, please email me at sajidiqbal.pk@gmail.com

- 1 2.3.7 Image Region
- 2 A group of connected pixels that have similar properties and are treated as unit in computation is known
- 3 as region or in other words a connected component is also referred as *Region*.
- 4 2.3.8 Adjacent and Disjoint Regions
- 5 Two regions Ri and Rj are called adjacent if RiURj form a connected set. Regions that are not adjacent
- 6 are said to be *disjoint*.
- 7 2.3.9 Image foreground and background
- 8 If an image has K regions $R_1, R_2, ..., R_k$ then $R_1 \cup R_2 \cup ... \cup R_k$ forms the foreground of image whereas
- 9 its complement is called the background.

Foreground =
$$\{R_1 \cup R_2 \cup ... \cup R_k\}$$
 2-8

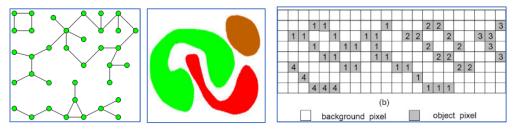

11

12
$$Background = \{R_1 \cup R_2 \cup ... \cup R_k\}'$$
 2-9

13 14

$$Background = image - \{R_1 \cup R_2 \cup ... \cup R_k\}$$
 2-10

15

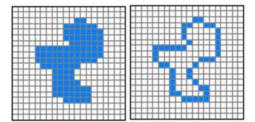

16 17

18

Figure 2-13: A) Connected components B) Disjoint regions C) Image foreground and background

2.3.10 The Contour

- The boundary of an image is called the contour. A boundary of a region R is a collection of pixels in R
- 20 that are adjacent with its background (complement of region). We have to define the type of connectivity
- when calculating the contour i.e. $N_4(p)$ or $N_8(p)$.
- 22 Inner border refers to set of pixels in foreground that are adjacent to background
- 23 similarly outer border is the set of pixels that are adjacent to foreground. An edge is defined as set of
- 24 pixels with derivative values that precede some specific threshold.

25 26

Figure 2-14: A) Object in image B) Object contour

If you find any mistake in this text or you have any suggestions for improvement, please email me at

sajidiqbal.pk@gmail.com

1 2.3.11 Distance Measure

- 2 For many applications, we need to measure the distance between source and destination pixels. There
- 3 are number of distance measures used in this context however only three are discussed here. To measure
- 4 the distance between two pixels following conditions must be satisfied:
 - $D(p,q) \geq 0$

5

13

- $\bullet \quad D(p,q) = D(q,p)$
- 7 $D(p,s) \le D(p,q) + D(q,s)$

8 2.3.11.1 Euclidean Distance

9 This distance between two pixels p(x, y) and q(u, v) is measured using following formula:

10
$$D_e(p,q) = \sqrt{(x-u)^2 - (y-v)^2}$$
 2-11

11 2.3.11.2 City Block Distance

12 It is also called the D_4 distance and is measured using following formula:

$$D_4(p,q) = |x - u| + |y - v|$$
 2-12

14 This distance measure forms the diamond like pattern of distances from reference point as shown below:

15
$$D_4(p,q_i) = \begin{vmatrix} 2 & 2 & 1 & 2 \\ 2 & 1 & 2 & 2 \\ 2 & 1 & 0 & 1 & 2 \\ 2 & 1 & 2 & 2 \end{vmatrix}$$

16 2.3.11.3 Chessboard Distance

17 This measure is also called the D_8 distance and is measured using formula:

18
$$D_8(p,q) = \max(|x-u|,|y-v|)$$
 2-13

20 And it forms a rectangular like pattern for distances from reference point. As an example, for $D \le 2$ the

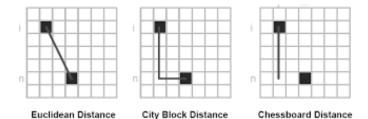

21 pattern looks like this

$$D_8(p,q_i) = \begin{vmatrix} 2 & 2 & 2 & 2 & 2 \\ 2 & 1 & 1 & 1 & 2 \\ 2 & 1 & 0 & 1 & 2 \\ 2 & 1 & 1 & 1 & 2 \\ 2 & 2 & 2 & 2 & 2 \end{vmatrix}$$

23

22

19

24 25

1 2.3.11.4 Statistical distances

- 2 There are multiple ways to find distances between two quantities that you will encounter during the
- 3 study of image processing and computer vision. We list here few of them without any details:
 - Mahalanobis distance
 - Bhattacharyya distance
- Energy distance
- Signal to noise ratio distance
- 8 We will discuss these distances later in the text where we will use them.

16 2.4 Basic Mathematics for Digital Image Processing

- 17 It has been observed that computer science students usually avoid mathematics. However, computing
- 18 stands for mathematics so a computer scientist must convince himself to understand and program
- mathematics. Digital image processing requires some initial mathematics and we will review it here in this
- 20 context. The reader of this text must have observed that an image is matrix of unsigned discrete values.
- 21 So, we will perform some matrix operations.
- 22 2.4.1 Elementwise matrix operations
- 23 Element wise operations means that each element of matrix must be applied some operations
- individually. Simplest operation is adding a scalar element in each pixel value in an image as shown here:

25
$$A = \begin{bmatrix} 1 & 1 & 1 \\ 2 & 2 & 2 \\ 3 & 3 & 3 \end{bmatrix} \rightarrow A + 5 = \begin{bmatrix} 6 & 6 & 6 \\ 7 & 7 & 7 \\ 8 & 8 & 8 \end{bmatrix}$$

- 26 2.4.2 Matrix Operations
- 27 We can also perform different matrix operations easily using python vector computing capabilities. For
- 28 example, following two matrices can easily be added together using single python statement.

Input matrices		Result	Python Statement
$A = \begin{bmatrix} 1 & 1 & 1 \\ 2 & 2 & 2 \\ 3 & 3 & 3 \end{bmatrix}, B = \begin{bmatrix} 6 & 6 \\ 7 & 7 \\ 8 & 8 \end{bmatrix}$	6 7 8	$A + B = \begin{bmatrix} 7 & 7 & 7 \\ 9 & 9 & 9 \\ 11 & 11 & 11 \end{bmatrix}$	img1+img2

If you find any mistake in this text or you have any suggestions for improvement, please email me at sajidiqbal.pk@gmail.com

1

2

2.4.3 Linear vs Non-Linear Operations

An operation β is called a linear operation if it fulfills following properties:

$$\beta[af_1(x,y) + bf_2(x,y)] = a\beta f_1(x,y) + b\beta f_2(x,y) = ag_1(x,y) + bg_2(x,y)$$
2-14

5 6

4

There are two properties that must be satisfied for linear operation.

7 8 Additivity: This equation tells that an operation applied on sum of two terms must be equal to
applying that operation on individual term and them summing them.

9

• *Homegeneity*: the output of a linear operation on a constant multiplied by an input is the same as the output of the operation due to the original input multiplied by that constant

10

11

If an operation fails to satisfy these two conditions, is called the non-linear operation

12 2

- 2.4.3.1 Arithmetic Operations
- Followings are few arithmetic operations that can be performed on two images f(x,y) and g(x,y)
- 14 (matrix operations)

Operation	Mathematical Equation	
Sum	S(x,y) = f(x,y) + g(x,y)	2-15
Difference	D(x,y) = f(x,y) - g(x,y)	2-16
Product	P(x,y) = f(x,y) * g(x,y)	2-17
Division	$V(x,y) = f(x,y) \div g(x,y)$	2-18

15

- An arithmetic operation can be used to extract different features from the images. For example, removing
- 17 noise from noisy images and finding the change in an image. Image subtraction is normally used in mask
- 18 mode radiography in which first a patient is imaged and this image is named as mask. Then a contrast
- agent is injected into the body of patient and patient is imaged again. The new image is then subtracted
- from original image (image taken without injection) that gives the change caused due to contrast agent.
- 21 Image multiplication and division can be used for shading correction present in an image.

22 2.4.3.2 Set Operations

- 23 A set is collection of distinct objects. If we denote a set with S and its object with ai where i is the index
- of elements then a set can be written as $S = \{a_0, a_1, a_2, ..., a_n\}$. Following list shows different concepts
- associated with sets.
- 26 27
- Set membership: $a_i \in S$ denotes that element a_i belongs to set S and $a_i \notin S$ denotes that a_i does not belong to set S
- 28 29
- Cartesian Product: It is defined over two sets A, B and is a set of all ordered pairs in which first element of each pair is from set A and second element is from set B.

30 31

$$AXB = \{(a, b) | a \in A, b \in B\}$$
 2-19

If you find any mistake in this text or you have any suggestions for improvement, please email me at sajidiqbal.pk@gmail.com

- Subset of a set: If every element of set T is member of Set S then T is said to be the subset of S and denoted as $T \subseteq S$.
- Union: Union of two sets A and B is a set that contains all elements of both sets and denoted as
 A ∪ B. For images union operations can be defined as

$$A \cup B = \{ \max_{z} (A, B) | a \in A, b \in B \}$$
 2-20

• Intersection: Intersection of two sets A and B is a set that contains elements which are common in both sets and denoted as $A \cap B$.

9
$$A \cap B = \{ \min_{z} (A, B) | a \in A, b \in B \}$$
 2-21

- Disjoint or Mutually Exclusive: If two sets A and B have no common element, they are called disjoint sets and their intersection is empty set $A \cap B = \emptyset$.
- Sample Space Ω : It is the set of all possible subsets for a given set S. For an image, the sample space is set of all pixels of that image.
- Set Complement: complement of set A is all the elements that are not in A.

15
$$A^c = \{w | w \notin A\}$$
 2-22

• Set Difference: The difference of two sets A, B consists of all elements that are in A and are not in B.

$$A - B = \{ w | w \in A \land w \notin B \}$$
 2-23

There are some other set operations that are listed in following table.

21 Table 3: Set operation

Law Name	Mathematical Notation	
Commutative	$A \cap B = B \cap A$	2-24
Law	$A \cup B = B \cup A$	2-25
Associative Law	$(A \cup B) \cup C = A \cup (B \cup C)$	2-26
	$(A \cap B) \cap C = A \cap (B \cap C)$	2-27
Distributive Law	$A \cup (B \cap C) = (A \cup B) \cap (A \cup C)$	2-28
	$A \cap (B \cup C) = (A \cap B) \cup (A \cap C)$	2-29
DeMorgan's Law	$(A \cup B)^C = A^C \cap B^C$	2-30
	$(A \cap B)^{\mathcal{C}} = A^{\mathcal{C}} \cup B^{\mathcal{C}}$	2-31

2.4.3.3 Logical Operations

The operations that results in TRUE or FALSE are called the logical operations. An image generated through logical operations is a binary image. The pixels with values TRUE are shown as white and those with value FALSE are shown as black. A set containing pixels with TRUE value forms the *foreground* of image and the set with FALSE value pixels forms the *background* on the image. To perform logical operations two

If you find any mistake in this text or you have any suggestions for improvement, please email me at

sajidiqbal.pk@gmail.com

- 1 images are required (Except *Not* operation). An image with varying values of pixels can be considered as
- 2 binary image if we consider zero values as FALSE and non-zero values as TRUE. Few of the logical
- 3 operations are listed below:

Table 4: Logical Operations

Logical operation	Description
AND	A AND B: The result is the set of pixels that is defined as
	$A \cap B = \{ \min_{z} (A, B) a \in A, b \in B \}$
OR	A OR B: This operation is similar to union operation of images
	$A \cup B = \{ \max_{z} (A, B) a \in A, b \in B \}$
NOT	NOT A: Zero values in the image A are converted to non-zero values and vice versa

5 6

21

23

4

2.4.3.4 Spatial Operations

- 7 These are the operations that are performed directly on the values of image pixels. The operations that 8 we have seen till now are all spatial operations. These operations can be categorized as:
- 9 Single pixel operations
- Neighborhood operations
- Geometric spatial transformations

12 Single Pixel Operations (SPO)

- 13 Single pixel operations are performed on each pixel separately without considering value of other pixels
- in the image. The operation is denoted as s = T(z). Where T some operation (transformation). For
- example, if A represents an image, then 2 * A operation multiplies each pixel with value 2 that is a
- 16 transformation.

17 Neighborhood Operations (NHO)

- 18 These are the operations that consider the pixel neighborhood to transform it to some new value. This
- may be N_4 , N_8 or any other user defined. As an example, let we define a window of 8 pixels that is used
- 20 to find the new value of its center pixel.

Example 2-2: NHO Transformation

22 The NHO transformation could be as follows:

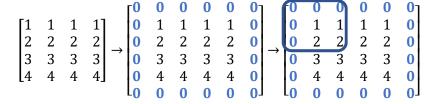

Figure 3-2: A) Matrix B) Matrix with zero padding C) First averaging window in matrix

If you find any mistake in this text or you have any suggestions for improvement, please email me at sajidiqbal.pk@gmail.com

Averaging Window	Resulting Matrix	Averaging window	Resulting Matrix
$\begin{bmatrix} 0 & 0 & 0 \\ 0 & 1 & 1 \\ 0 & 2 & 2 \end{bmatrix}$	$\begin{bmatrix} \frac{6}{9} = 0.67 \\ \end{bmatrix}$	$\begin{bmatrix} 0 & 0 & 0 \\ 1 & 1 & 1 \\ 2 & 2 & 2 \end{bmatrix}$	$\begin{bmatrix} 0.67 & \frac{9}{9} = 1 \\ \end{bmatrix}$
$\begin{bmatrix} 0 & 0 & 0 \\ 1 & 1 & 1 \\ 2 & 2 & 2 \end{bmatrix}$	$\begin{bmatrix} 0.67 & 1 & \frac{9}{9} = 1 \\ & & & \end{bmatrix}$	$\begin{bmatrix} 0 & 0 & 0 \\ 1 & 1 & 0 \\ 2 & 2 & 0 \end{bmatrix}$	[0.67 1 1 0.67]
$\begin{bmatrix} 0 & 1 & 1 \\ 0 & 2 & 2 \\ 0 & 3 & 3 \end{bmatrix}$	[0.67 1 1 0.67 1.33	$\begin{bmatrix} 1 & 1 & 1 \\ 2 & 2 & 2 \\ 3 & 3 & 3 \end{bmatrix}$	[0.67 1 1 0.67 1.33 2

1

2

3

4

First, we padded the original matrix with zeros by introducing zero rows and zero-columns. Each 3x3 windows is averaged using formula (indexing is done when window is extracted from image and reindexed):

5
$$g(x,y) = \left(\frac{1}{3X3}\right) \sum_{1}^{3} \sum_{1}^{3} f(x,y) = \frac{1}{9} \sum_{1}^{3} \sum_{1}^{3} f(x,y)$$
 2-32

6 By following this pattern, we can generate the final matrix that is

$$\begin{bmatrix} \mathbf{0} & \mathbf{0} & \mathbf{0} & \mathbf{0} & \mathbf{0} & \mathbf{0} \\ \mathbf{0} & 1 & 1 & 1 & 1 & \mathbf{0} \\ \mathbf{0} & 2 & 2 & 2 & 2 & \mathbf{0} \\ \mathbf{0} & 3 & 3 & 3 & 3 & \mathbf{0} \\ \mathbf{0} & 4 & 4 & 4 & 4 & \mathbf{0} \\ \mathbf{0} & \mathbf{0} & \mathbf{0} & \mathbf{0} & \mathbf{0} & \mathbf{0} \end{bmatrix} \rightarrow \begin{bmatrix} 0.67 & 1 & 1 & 0.67 \\ 1.33 & 2 & 2 & 1.33 \\ 2 & 3 & 3 & 2 \\ 1.56 & 2.33 & 2.33 & 1.56 \end{bmatrix}$$

8 9

13

7

Geometric Operations (GO)

- 10 These are also known as rubber sheet transformation. The name is given as application of such
- transformation do not bring any change in structure of image however the shape of image is changed.
- 12 Geometric transformations of digital images consist of two basic operations:
 - 1. Spatial transformation of coordinates.
- 14 2. Intensity interpolation that assigns intensity values to the spatially transformed pixels.
- 15 Such a transformation can be expressed as:

$$\begin{bmatrix} x' \\ y' \end{bmatrix} = T \begin{bmatrix} x \\ y \end{bmatrix} = \begin{bmatrix} t_{11} & t_{12} \\ t_{21} & t_{22} \end{bmatrix} \begin{bmatrix} x \\ y \end{bmatrix}$$
 2-33

- Where (x, y) are pixel coordinates in original image and (x', y') are transformed coordinates.
- 18 We will be mostly interested in affine transformations that include scaling, translation, rotation and
- sheering. It is the property of such transformation that they maintain the positions of points, corners,

If you find any mistake in this text or you have any suggestions for improvement, please email me at

sajidiqbal.pk@gmail.com

straight lines and planes. It is possible to use homogeneous coordinates to express all four affine transformations. It is done by using a single 3x3 matrix as given below:

$$\begin{bmatrix} x' \\ y' \\ 1 \end{bmatrix} = A \begin{bmatrix} x \\ y \\ 1 \end{bmatrix} = \begin{bmatrix} t_{11} & t_{12} & t_{13} \\ t_{21} & t_{22} & t_{23} \\ t_{31} & t_{32} & t_{33} \end{bmatrix} \begin{bmatrix} x \\ y \\ 1 \end{bmatrix}$$
 2-34

4 5

6

7

- This transformation can handle all four operations i.e. scaling, rotation, translation and shearing depending upon the values chosen for matrix A. In following table, we provide for this affine matrix A to implement different geometric operations.
- 8 Table 5: Image geometric transformations

Transformation Name	Affine Matrix (A)	Coordinate Equations
Identity	1 0 0 0 1 0 0 0 1	x' = x $y' = y$
Scaling / Reflection	$egin{array}{cccc} c_x & 0 & 0 \\ 0 & c_y & 0 \\ 0 & 0 & 1 \\ \end{array}$	$x' = c_x x$ $y' = c_y y$
Rotation	$\begin{array}{cccc} cos\theta & -sin\theta & 0 \\ sin\theta & cos\theta & 0 \\ 0 & 0 & 1 \end{array}$	$x' = x\cos\theta - \sin\theta$ $y' = x\sin\theta + y\cos\theta$
Translation	$\begin{array}{cccccccccccccccccccccccccccccccccccc$	$x' = x + t_x$ $y' = y + t_y$
Shear (Vertical)	$egin{array}{cccc} 1 & s_{v} & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \\ \end{array}$	$x' = x + s_v y$ $y' = y$
Shear (horizontal)	$egin{array}{cccccccccccccccccccccccccccccccccccc$	$x' = x$ $y' = s_h x + y$

9

10 Following figure shows that how the sheer vertical operation works.

2.4.3.5 Image Registration

Image registration is used to align two or more images of same scene. In this process, we have a reference image that is used to align the input images. In affine transformations, the mapping function is known however in image registration such a function is not - known and need to be estimated. The registration is required in two cases usually:

- Image registration for images taken at same time by using different instruments. Examples of image registration include aligning two or more images taken at approximately the same time, but using different imaging systems, such as an MRI (magnetic resonance imaging) scanner and a PET (positron emission tomography) scanner.
- Or, perhaps the images were taken at different times using the same instruments, such as satellite images of a given location taken several days, months, or even years apart.
- Stitching various scene images to form a continuous panoramic shot. Google maps and google earth use this image processing feature.
- Aligning document images which may be have geometric transforms like rotation or scaling, to form a standard realistic view of scanned document

In either case, combining the images or performing quantitative analysis and comparisons between them requires compensating for geometric distortions caused by differences in viewing angle, distance, orientation, sensor resolution, shifts in object location, and other factors.

- 21 A good approach is to use the control points (tie-points) in both images. Tie-points are the points
- 22 in both images whose locations are precisely known. Researchers have developed algorithms to find such
- tie-points automatically. Even some imaging systems have physical artifact embedded in the imaging
- 24 system such as pins, screws. Such embedded points are known as *reseau marks* or *fiducial marks*.
- The known points can be used as guide to mark the tie-points in the image.
- Let we explain the process with the help of an example. Let we have four tie-points in both images as listed below:

Input image	Reference image
$(v_1, w_1), (v_2, w_2)(v_3, w_3), (v_4, w_4)$	$(x_1, y_1), (x_2, y_2), (x_3, y_3), (x_4, y_4)$

If you find any mistake in this text or you have any suggestions for improvement, please email me at

sajidiqbal.pk@gmail.com

1 And let the mapping between these corresponding points is given by following model:

X points in reference image	Y points in reference image	
$x_1 = c_1 v_1 + c_2 w_1 + c_3 v_1 w_1 + c_4$	$y_1 = c_5 v_1 + c_6 w_1 + c_7 v_1 w_1 + c_8$	2-35
$x_2 = c_1 v_2 + c_2 w_2 + c_3 v_2 w_2 + c_4$	$y_2 = c_5 v_2 + c_6 w_2 + c_7 v_2 w_2 + c_8$	
$x_3 = c_1 v_3 + c_2 w_3 + c_3 v_3 w_3 + c_4$	$y_3 = c_5 v_3 + c_6 w_3 + c_7 v_3 w_3 + c_8$	
$x_4 = c_1 v_4 + c_2 w_4 + c_3 v_4 w_4 + c_4$	$y_4 = c_5 v_4 + c_6 w_4 + c_7 v_4 w_4 + c_8$	

2

4

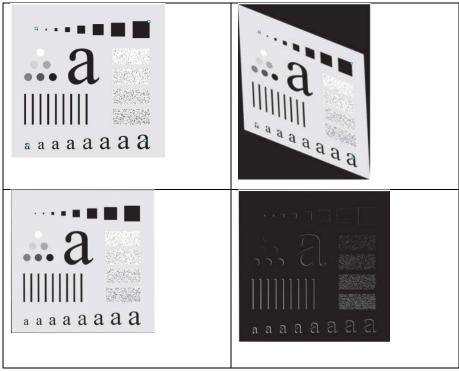

5

6

7

By solving these equations, we can easily find the values of coefficients *cs.* Once these coefficients are found, all of input image pixels are transformed to reference image and the result is the desired registered image. The correctness of result is based on selection of correct tie-points. If the image is complex, it can be broken sub parts and each sub part is worked independently. Following is good example of registration taken from Gonzalez's Book (Digital Image Processing, FOURTH EDITION, Rafael C. Gonzalez • Richard E.

- 8 Woods).
- 9 Table 6: A) Reference Image B) Distorted Input Image C) Registered Input Image D) Difference of A and C

10

11

12

13

14

15

Figure 2-17: Image Registration

A better method to perform image registration is to use image features and match them. Each image possesses different features like number of objects, edges, corners, mean intensity values and intensity variance. Instead of finding tie-points, we can extract features and match them. The topic of feature extraction is an advanced one at this stage so we leave its detail at this stage and provide the program which is explained accordingly. For two images, one as template image and other to be matched with

3

10

11

17

27

If you find any mistake in this text or you have any suggestions for improvement, please email me at sajidiqbal.pk@gmail.com

template, convert both images to gray scale so that their feature extraction and matching process could 1 2 be easy and efficient.

- Find the key points in both images and their locations. These key points could be considered as tie-points.
- Find the descriptors of both images. *Descriptors* are the quantities that give information about the image like image mean, variance and histogram bins.
- Compare these key points and descriptors of both images. There are multiple algorithms that can be used for extracting key-points and their relevant descriptors.
- Keep the high value matches and filter out low value matches
- Find a homography transform.
 - Apply this transform to input image that will align it with reference image

12 2.4.3.6 The Homography transform

13 It is popular geo-referencing technique that is based on complex geometric and mathematic concept

14 known as "homogenuous coordinates" and "projective planes". Instead of explaining the process in detail,

15 we will provide only an overview.

16 We know that Cartesian plane has two axis x and y.

The plane is composed of points and each point is

18 represented with two real values, one for x and one

19 for y. A "projective plane" can be considered as a

20 superset of Cartesian plane that is composed of

21 points and in addition to that there are all possible

22 straight lines in the direction of space (z-direction).

23 The concept is originated from the visual effect of

24 perspective where parallel lines seem to meet on

25 infinity as shown in the figure.

26 The projective space is also called the affine space.

Just looking at the picture, one can "perceive" that

these parallel lines will cross each other on some

28

29 point at infinity. Similarly, generalizing the concept, 30 there will be one point at infinity in each direction. It

31 is important to know that in cartesian plane, lines

32 may intersect each other at most at one point (may 33 or may not intersect) but in projective plane they

34 intersect each other at exactly one point. Such a

35 point exists at infinity if the lines are parallel. If two

36 planes P1 and P2 are parallel to each other in space,

38 plane, there may be infinite number of lines that pass through p and map to some point in P2 blue (upper)

39 plane.

40 Homography is the concept which tells that for each point in plane P1, there will be a corresponding point 41

in P2. If there are four points in P1, there will be four points in P2. It helps to map (register) one image to

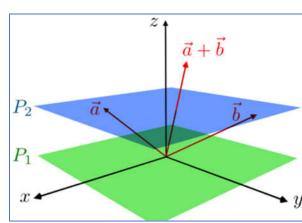

Figure 2-18: A) Parallel lines B) Parallel planes

If you find any mistake in this text or you have any suggestions for improvement, please email me at

sajidiqbal.pk@gmail.com

- 1 other. The homography transformation method has been extended to maps when aerial photographic
- 2 techniques have been used. The homography transform is based on following formulas:

$$X = \frac{ax + by + c}{gx + hy + 1} \qquad and \qquad Y = \frac{dx + ey + f}{gx + hy + 1}$$
 2-36

- 4 Here X, Y are the coordinates of second plane and x, y are the coordinates of the first plane.
- 5 2.4.3.7 Vector and Matrix Operations
- 6 A color image consists of three channels and could be considered as 3D image. There are image formats
 - that can contain more than three channels like MRI slices that may be more than 100 depending upon the
- 8 capability of imaging device. A multi-spectral (MS) image is one that is captured using multiple frequencies
- 9 of EM spectrum. In such MS images, vector and matrix operations are used routinely. In order to
- understand the vector operations, we consider color images that contain 3 spectral parts i.e. red, green
- and blue. Each pixel in color image, therefore, contains 3 values: $f(x,y) = (I_{red}, I_{areen}, I_{blue})^T$ or
- equivalently it can be represented as $\mathbf{z} = [z1 \ z2 \ z3]^T$. We write it as transpose to clear that it is not spatial
- 13 representation but transposed version of that representation. Pixel value in an image with n slices can be
- 14 represented as $\mathbf{z} = [z_1 \ z_2 \ z_3 \dots \ z_n]^T$
- 15 Inner product is defined as

16 17

18

7

$$\mathbf{a} \cdot \mathbf{b} = \mathbf{a}^{\mathsf{T}} \mathbf{b} = a_1 b_1 + a_2 b_2 + \dots + a_n b_n = \sum_i a_i b_i$$
 2-37

Example 2-3: Inner product via matrix multiplication

- 19 To make the concept clear, we provide here an example.
- Let A = [1,2,3] and B = [4,5,6] then its inner product is given as:

21
$$A \cdot B = 1 * 4 + 2 * 5 + 3 * 6 = 4 + 10 + 18 = 32$$

22 Now we solve same using vector notation:

$$A = \begin{bmatrix} 1 \\ 2 \\ 3 \end{bmatrix} \text{ and } B = \begin{bmatrix} 4 \\ 5 \\ 6 \end{bmatrix}$$

$$A^T \cdot B = \begin{bmatrix} 1 & 2 & 3 \end{bmatrix} \cdot \begin{bmatrix} 4 \\ 5 \\ 6 \end{bmatrix}$$

$$= 1 * 4 + 2 * 5 + 3 * 6 = 4 + 10 + 18$$

= 32

2728

31

32 33

Vector Norms

- A norm is a function that assign positive value to a vector this value is length or size of vector. There are multiple types of norms which are used in vector processing.
 - 1. Absolute Value Norm (L1 Norm): It is the norm for one dimensional vector. If x is some vector, Absolute value norm is denoted as ||x|| or |x|.
 - 2. Euclidean Norm: for some vector \mathbf{x} it is denoted as

If you find any mistake in this text or you have any suggestions for improvement, please email me at

sajidiqbal.pk@gmail.com

1 $||x||_2 = |x|_2 = \sqrt{x_1^2 + x_2^2 + x_3^2 + \dots + x_n^2}$ 2-38

Three are different names used for Euclidean Norm that may include Euclidean Length, L^2 Distance and L^2 norm. A Euclidean norm is square root of inner product (length of vector \mathbf{z}) that is

$$\|\mathbf{z}\| = (\mathbf{z}^T \mathbf{z})^{\frac{1}{2}}$$
 2-39

3. Euclidean Distance between two vectors (\mathbf{z}, \mathbf{a}) can be written as

$$D(z,a) = ||z-a|| = [(z-a)^T(z-a)]^{\frac{1}{2}}$$
 2-40

$$= [(z_1 - a_1)^2 + (z_2 - a_2)^2 + \dots + (z_n - a_n)^2]^{\frac{1}{2}}$$
2-41

2.4.3.8 Image Transforms

The approaches discussed till now are based on spatial domain processing. There are situations when image processing can become efficient by transforming the image into some other domain (transform domain). You can consider a transform domain as way of image representation. For example, you can represent the location of a pixel in an image either using rectangular coordinates (x, y) or polar coordinates (x, y) where

15
$$r^2 = x^2 + y^2$$
 and $\theta = \tan^{-1} \frac{y}{x}$ 2-42

16 And

5

6

7

8

9

10

11

12

13

14

28 29

30

31

32

33

$$x = r\cos\theta \quad and \quad y = r\sin\theta \qquad 2-43$$

By having this knowledge, we look at general form of $transform\ domain$. Let f(x,y) is an image in spatial domain and (u,v) are coordinates or transform variables of transform domain T(u,v).

20
$$T(u,v) = \sum_{x=0}^{M-1} \sum_{y=0}^{N-1} f(x,y)r(x,y,u,v)$$
 2-44

- Here you can see that for every pixel of image, pixel value f(x,y) is transformed using r(x,y,u,v) and then multiplied with original image pixel value. Such transformation-product values are summed for all rows and columns of image. You can observe transformed value of a pixel is different from its corresponding value in original spatial domain. This is called the **forward transformation** and r(x,y,u,v)
- 25 is called the *forward transformation kernel*.
- By rearranging the equation, we can obtain pixel original value f(x, y) from T(u, v) as follows:

27
$$f(x,y) = \sum_{x=0}^{M-1} \sum_{y=0}^{N-1} T(u,v)s(x,y,u,v)$$
 2-45

where s(x, y, u, v) is called an *inverse transformation kernel*. Both equations combinedly are named as *transform pair*. There are number of transform domains that may include Walsh, Hadamard, slant, $discrete\ cosine\ and\ Haar\ transforms$. You will encounter may such transformation when working with image processing. Although there are built in software routines available however being a student of digital image processing course, you should try to code them yourself.

If you find any mistake in this text or you have any suggestions for improvement, please email me at

sajidiqbal.pk@gmail.com

1 2.4.3.9 Separable Kernel

2 A kernel (vector or matrix) can be written as product of two vectors/matrices, it is called separable kernel.

3
$$r(x, y, u, v) = r_1(x, u)r_2(y, v)$$
 2-46

4

A kernel is said to be *symmetric* if $r_1(x, u)$ is functionally equivalent to $r_2(y, v)$ i.e.

6
$$r(x, y, u, v) = r_1(x, u)r_1(y, v)$$
 2-47

7 Example 2-4: Separable Kernel

8 Following kernel can be represented as product of two simpler kernels, hence it is separable kernel.

$$\begin{bmatrix} 1 & 0 & -1 \\ 2 & 0 & -2 \\ 1 & 0 & -1 \end{bmatrix} = \begin{bmatrix} 1 \\ 2 \\ 1 \end{bmatrix} * \begin{bmatrix} 1 & 0 & -1 \end{bmatrix}$$

10

- 11 2.4.3.10 Image Intensities as Random Variables
- 12 Probability theory is very useful tool when working with random experiments. If we consider value of each
- pixel in an image independent of other pixels, a random variable can be used to represent image pixels.
- Here we list few basic concepts of probability in context of image processing. Let there be L levels of
- intensity in an image and Z_i represents the intensity value of a pixel for L levels where i=0,1,2,3,...,L-1
- 16 1. If there are M rows and N columns in an image then.
- 17 4. Probability of z_i level

$$p(z_i) = \frac{n_i}{MN}$$
 2-48

19

- where n_i is number of pixels having intensity level i.
- 5. *Total probability* of all intensity levels.

$$\sum_{i} \frac{n_i}{MN} = 1$$

23 6. *Image mean intensity*

$$m = \sum_{i} z_i p(z_i)$$
 2-50

25

26 7. variance of image intensities

$$\sigma^{2} = \sum_{i} (z_{i} - m)^{2} \ p(z_{i})$$
 2-51

28

- Central moments of a random variable are very useful measure that provide good insight of image
 intensity distributions. Center moment is quantitative measure of shape of a function about its mean
- 31 value. Image moments are useful to describe objects after segmentation. Simple properties of the

2.5 Image Interpolation

- 2 Estimating the unknown pixel values using known pixel values is called interpolation. There are multiple
- 3 situations where image interpolation is required. These image operations may include the zooming,
- 4 shrinking and rotating. A number of interpolation algorithms have been presented in literature.
 - Nearest neighborhood interpolation
 - Bilinear interpolation
 - Bicubic interpolation
- 8 There are some variants of these interpolation methods that include
 - Resampling using pixel area relation
- Bit exact bilinear interpolation
 - Mask based interpolations
- Trilinear interpolation
- Spline interpolation
- Lanczos resampling
- Stairstep interpolation
 - Barycentric coordinates for interpolating within a triangle or tetrahedron
- 17 In this section we only explain nearest neighborhood interpolation.
- 18 2.5.1 Nearest neighborhood interpolation
- 19 This method simply determines the "nearest" neighboring pixel, and assumes the intensity value of it.
- 20 First, let's consider this in a 1-dimensional case. Observe the plot below:

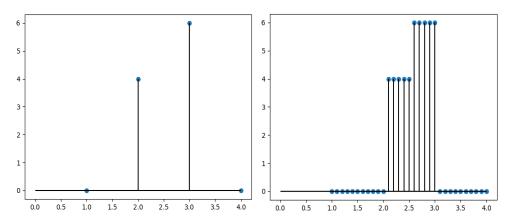

Figure 2-21: Nearest neighborhood interpolation A) Original Data B) Interpolated Data

Let's say that we want to insert more data points between the points x1 = 2 and x2 = 3 where f(x1) = 4 and f(x2) = 6 as shown in the figure by solid black lines and their blue tips. Using nearest neighborhood our result will look like the figure 2-12 B. In Figure 2-12 B, you can see that between two points x1=2 and x2=3, we have inserted 7 points and assigned each point same intensity value as that of its nearest neighbor.

Now we extend this concept to 2D plane. Let we have a 2x2 image that we want to zoom to 4x4. This image *upsampling* is done as:

2.6 Exercises

2

1

1. Q.No.1 Consider the following matrices

$$A = \begin{bmatrix} 0 & \boxed{3} & 1 & 3 \\ 2 & 1 & 2 & 3 \\ 3 & 0 & 0 & 1 \\ 1 & 0 & 2 & 3 \end{bmatrix}$$

$$B = \begin{bmatrix} 0 & 3 & 1 & 3 \\ 2 & 1 & 2 & 3 \\ 3 & 0 & 0 & 1 \\ 1 & 0 & 2 & 3 \end{bmatrix}$$

5 6

7

Let $L = \{0,1,2,3\}$ then if $V_1 = \{0,1\}$, $V_2 = \{0,1,2\}$, $V_3 = \{0,1,2,3\}$ write a program to find the m-adjacency of circled pixels.

- 8
- 2. Discuss the m-adjacency if $v = \{1,2\}$ and pixels are given as follows:

 $\begin{bmatrix} 0 & 1 & 1_q \\ 0 & 2_p & 0 \\ 0 & 0 & 1 \end{bmatrix}$

10 11

12

3. Write a program to compare two images using image subtraction. Read an image from user and create its two copies, create some noise using numpy and add this noise to a copy of original image. Now subtraction noisy image from actual image. It will give you the change in image.

13 14 15

4. Write a program in python that reads three images and verify the set laws given in table-3 visually. i.e. perform these operations on images and shows that LHS=RHS

28 29

30

16

- 5. write a program that generates the output image using 3x3 averaging, mean and mode window on input image
- 20 6. Write a python program to perform all four transformations on input image
 - 7. Write a program to register user given images
 - 8. Write a python program to calculate the basic statistics, given in table 7, about an input image. Do not use any library method. Use only python language for computation.
 - 9. Write a python program to find nth moment of given image. Also draw the distribution of image pixel intensities and discuss your quantitative results with visual results.
 - 10. Write a program to find the path between two pixels. (Hint: you may consider Breadth First Search method)
 - 11. Write a program to find the boundary in an image. Also find inner border and outer border of an object in an image. You should suppose that the image has only one foreground object on black background.

31 12.
